Although there is some evidence that scrubs, masks, and head coverings reduce bacterial counts in the operating room, there is no evidence that these measures reduce the prevalence of surgical site infection. The use of gloves and impervious surgical gowns in the operating room reduces the prevalence of surgical site infection. Operating-room ventilation plays an unclear role in the prevention ...

This project focuses on the complexities of surgical attire as a component of the environmental performance of a hospital. The three studies in this dissertation offer different types of

analyses to provide a holistic perspective on the surgical attire market from the perspective of customer (textile user) preferences, policy and regulatory constraints, and resource use efficiency. The first study conducted three rounds of warm-up jacket trials and questionnaires that included questions about satisfaction with 11 characteristics of warm-up jackets, specific problems with the jacket characteristics rated as unsatisfactory, demographic items, and overall ranking of the jackets. The main objective is to determine the characteristics of each jacket that influence staff's preferences among the jackets. An initial sample of 46 participants completed at least one round of jacket trial and survey, but only 13 people completed all three surveys for various reasons. Rank ANOVA models indicated that 8 of the 11 characteristics were significantly related to the overall preference rankings. Fisher's exact test on reported problems for each jacket found that for 7 of the 21 categories of problem types, there was a significant difference in frequency of problems by jacket. A regression tree analysis was run to identify cutoffs for age that corresponded to major shifts in preference for disposable versus reusable warm-up jackets in general. Limitations of the study include a small sample size, an order effect from trialing the jackets in the same sequence, and a potential bias for reusable jackets as the hospital communicated consideration of transitioning to reusable jackets from the currently worn disposable types. The second study is a policy analysis looking at the constraints hospitals face when considering the adoption of innovative textile products that do not meet the cited technology standards met in order to obtain proper accreditation and payments for services. A matrix of organizations involved in the management of surgical attire at the hospital was categorized by the type of policy instrument used to prescribe compliance and the influence it had on purchasing decisions. The majority of organizations influencing surgical attire decisions use inflexible technology standards that do not facilitate/permit innovation by manufacturers to address market issues, like the lack of product recyclability. Introducing incentives for innovation can drive the market to improve the environmental performance of hospitals. The third and final study conducts a material flow analysis (MFA) of the surgical attire processes required for the hospital to provide scrubs to the entire surgical staff. This study maps the flow of scrub garments throughout the process of purchase, use, delivery, laundry, and eventual disposal. A pre- and post-intervention model compared the processes before and after the technological (garment vending and collection machines) and garment management interventions to determine the impacts on three census points, where the process prior to intervention had high garment loss. The post-intervention system reduced loss at two census points and a material gain at the other census point. The new process documents more authorized users on a smaller total stock with more efficient storage, delivery, and collection procedures that save space and labor when compared to the pre-intervention procedures.
